

SF2.3: Age of mothers at childbirth and age-specific fertility

Definitions and methodology

This indicator contains information on the age of mothers at childbirth and levels of fertility across age groups. It is based on two main measures:

- *Mean age of mothers at birth*, calculated as the simple mean average age in years of women at childbirth. The mean age of mothers at birth is shown both for all births and also for first births only.
- *Age-specific fertility rates*, calculated as the number of births per 1000 women of a given age in a given year. As a means of simplification, age-specific fertility rates are presented here per five-year age group and with particularly focus on fertility among adolescent (15-19 year old) women.

Key findings

In the Asia/Pacific region as also in many OECD countries, the average age of women at childbirth has increased considerably in recent decades (Chart SF2.3.A). In 1970, among Asia/Pacific countries with available data, the mean age of women at childbirth ranged from 26.7 years of age in New Zealand to 29.1 in Malaysia and Singapore. Today, the mean age of women at birth is at least 30 in all covered Asia/Pacific countries with available data except Thailand, Indonesia and China, and reaches as high as 31.6 in Singapore and 31.9 in Korea. All covered countries have seen the mean age of women at childbirth increase over the intervening years, with the largest increases in Australia and New Zealand (3.7 years).

Increases in the mean age of women at childbirth have been driven at least in part by a trend towards postponement of the first birth (Chart SF2.3.B). Indonesia aside, current mean ages at first birth are generally fairly high in Asia/Pacific countries, though they do vary considerably from one country to another. In Indonesia, for example, the average age at which women give birth to a first child is 22, whereas in Korea it is as high as 31.2. However, all Asia/Pacific countries with available data have seen the average age at first birth increase since 1995. The largest increases have come in Korea (4.7 years) and especially Viet Nam, where the mean age of women at first birth in 2011 (30.1) was 6.3 years higher than it was in 1994 (23.8).

The shift towards the postponement of the first birth is also reflected in trends in adolescent fertility (Chart SF2.3.C). Current adolescent fertility rates vary somewhat across Asia/Pacific countries, from as low as 1.4 births per 1000 women aged 15-19 in Korea to 48 births per 1000 women aged 15-19 in Indonesia. However, in almost all cases the current rate is considerably lower than it was in 1995 and especially 1970. For example, in New Zealand, the adolescent fertility rate fell from 64 births per 1000 women aged 15-19 in 1970 to 33.4 in births per 1000 in 1995, and has since declined further to a current rate of 16.0 births per 1000 women aged 15-19. In Viet Nam, the adolescent fertility rate has fallen over 15 points just since 1995, from 46.3 to 31.1 births per 1000 women aged 15-19. The two exceptions to this broad trend are Japan, where adolescent fertility rates have remained fairly stable since 1970, and Thailand, where the rate fell between 1970 and 1995 but has since increased very slightly.

But the effects of the delay in childbearing are perhaps best illustrated by looking at shifts in fertility across age groups. Chart SF2.3.D shows, by country, age-specific fertility rates by five-year age groups for the years 1970, 1995 and 2016 (or nearest/latest available). Broadly, the chart shows both a postponement of birth and a general decrease in fertility for all covered Asia/Pacific countries. Across the covered countries, fertility rates among young women aged 15-19, 20-24 and especially 25-29 are much lower today than they were in 1970. Much of this decline occurred between 1970 and 1995, but in many countries fertility rates have continued to fall since 1995. Conversely, fertility rates for women aged 30-34 and 35-39 are in some countries (Australia, Japan, New Zealand) actually slightly higher now than they were in 1970, and in several Asia/Pacific countries (Australia, Japan, Korea, New Zealand, and Singapore) fertility rates among 30-34 year olds are currently higher than those for any other five-year age group.

Box LMF2.1.A: Childlessness

In many Asia-Pacific countries, as also in many OECD countries, childlessness is on the rise (Box Table SF2.3.A). During the early- to mid-1990s, in most of the covered Asia-Pacific countries, fewer than 5% of women aged 40-44 had never had a live birth. The only exceptions were Japan (11% of women were childless in 1995), New Zealand (12% of women were childless in 1996) and Australia (13% in 1996). However, by around 2010, all of the covered Asia-Pacific countries had childlessness rates at age 40-44 of 5% or higher. Among the covered countries, childlessness is least common in China where, in 2015, just less than 6% of women aged 40-44 were childless. It is most common in Australia, New Zealand and especially Japan, where 22% of women aged 40-44 were childless in 2010. Singapore and Thailand also had rates of around 10% in 2010.

Box Table SF2.3.A. Childless women at age 40-44, mid-1990s and 2010 or latest available year
 Proportion (%) of women aged 40-44 who have not had a live birth

	mid-1990s		2010 (or latest year)	
	%	Reference year	%	Reference year
Australia	12.80	1996	16.00	2011
China	0.98	1995	5.62	2015
Japan	10.67	1995	21.50	2010
Korea	3.60	1990	6.78	2005
New Zealand	11.90	1996	15.00	2006
Singapore	4.66	1990	9.30	2010
Thailand	4.42	1980	10.92	2010
Viet Nam

Notes: For Thailand, data refer to ever-married women only.

Comparability and data issues

The disaggregation of fertility rates by mother's age is useful as a means of identifying changes in the timing of fertility which, amongst other things, affect trends in the total fertility rate (SF2.1). The age-fertility profiles shown below show that women are postponing childbearing with fertility declining at younger ages and, for some countries, increasing at older ages. The consequences of these changes in timing on overall levels of fertility are not always exactly clear but postponement of childbirth is likely to lead to the underestimation of fertility as measured by the total fertility rate (Hvidtfeldt et al, 2010).

“Fertility rates by birth order”, “tempo-controlled estimates of fertility trends” and “the time between two births” are among the indicators that can help cast light on changes in the timing of fertility and help separate both the timing and quantum dimensions in the analysis of fertility evolution (see Potančoková *et al.* [2008] and other references below for a discussion in the context of fertility in European and OECD countries).
